

PROTECTING CONFIDENTIAL CLIENT INFORMATION. SOLVED.

WE GET NETWORK SECURITY

You need a network security solution that protects your firm not only from external threats, but from internal threats as well. We get that, and we're here to help. Our security solution architects will help you implement a layered security strategy that protects your firm from targeted attacks, viruses, spyware, rootkits, and zero-day attacks. A solution that reduces the need for emergency system patching, reduces patch-related downtime and cuts down on IT management expenses. A solution that protects you not only from existing threats – but from evolving threats as well.

The Stakes are high.

For a law firm, the effects of a cyber attack can be devastating. First of all, your firm's operations may be virtually shut down as you scramble to contain and mitigate the risk. Every minute your firm's administrators and attorneys can't do their normal work; it costs hundreds, if not thousands of dollars. If sensitive information is found to have been stolen or even accessed, your firm could face liability charges and fines. Then there's the damage this kind of attack can have on your firm's hard-won reputation.

If you think they're not after you, think again. Your clients, personal information, e-mail addresses, social security numbers and all of your firms' intellectual property resides within the confines of your network, which makes it a very attractive target for the bad guys.

Along with privacy concerns, maintaining the integrity of your data is also important, because customer contact records and other business information is often used in legal proceedings. Records that have become corrupt or inaccurate because of a security or network issue can result in a total breakdown of the process and significant losses to the firm.

Lock up your data.

Given the sensitivity and importance of the data that flows through your firm's infrastructure, it's no wonder that security has become a hot topic. With the number of security threats on the rise, a layered security approach has become an essential part of maintaining both privacy and integrity of your data. Whether you're a sole practitioner or a firm with more than 100 employees – when it comes to security, the rules are the same – security works best when it's in layers. The more layers you have, the safer your network is. These are the critical layers of protection:

Protection Against External Threats

- Intrusion prevention safeguards a network inside and out from lethal worm invasions and other malicious attacks
- Firewalls and virtual private networks secure Internet access points and guard network privacy
- Antivirus protection guards computers by automatically eliminating viruses, worms and Trojan horses
- Vulnerability scanning scans a network to identify – and dramatically reduce – the number of vulnerabilities

Protection Against Internal Threats

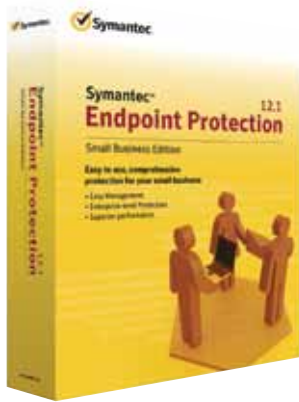

- Web and e-mail filtering enhances productivity while eliminating network and legal threats
- Event management monitors the security event logs on all Windows NT/2000/XP servers and workstations, alerting IT managers to internal intrusions or attacks in real time
